Bactericidal and fungicidal efficacy of dry steam

Study sponsored by GENERAL VAPEUR

Objective

Evaluation of the efficacy of dry steam treatment realised by menikini machines in order to clean surfaces contaminated by bacteria and fungi.

Reference

Trials were based on the European Regulation related to chemical disinfectants and antiseptics with the aim to evaluate the ability of dry steam to decrease bacterial and fungi contamination of surfaces.

List of EU rules:

EN 1040:2005 EN 1275:2006 EN 1276:2000 EN 1650:2000

Methods

One billion of colony forming units of each microorganism were uniformly distributed on a polymeric surface (as used in food industry), previously cleaned to remove any contamination. After the distribution of the test microorganism, the surface was treated with saturated dry steam. At the end of the treatment, bacteria on the surface and in the residual condensation liquid were sampled and lab analysed by sterile pads.

Results

In vitro trials demonstrated that the treatment with saturated dry steam was effective in the reduction of bacterial and fungal contamination of surfaces

The analytical values of bacterial and fungal contamination after treatment were always below the levels indicated by the EU rules that refer to a decrease of 10^4 UFC for fungicides and 10^5 UFC for bactericides.
